Tutorial: Hierarchical Bayesian Analysis for GW Population Inference

Amanda Farah

Structure of a hierarchical Bayesian analysis

Directed Acyclic Graph (DAG)

The joint (aka population) likelihood

- Observation of GWs from CBCs is an *inhomogeneous* Poisson process:

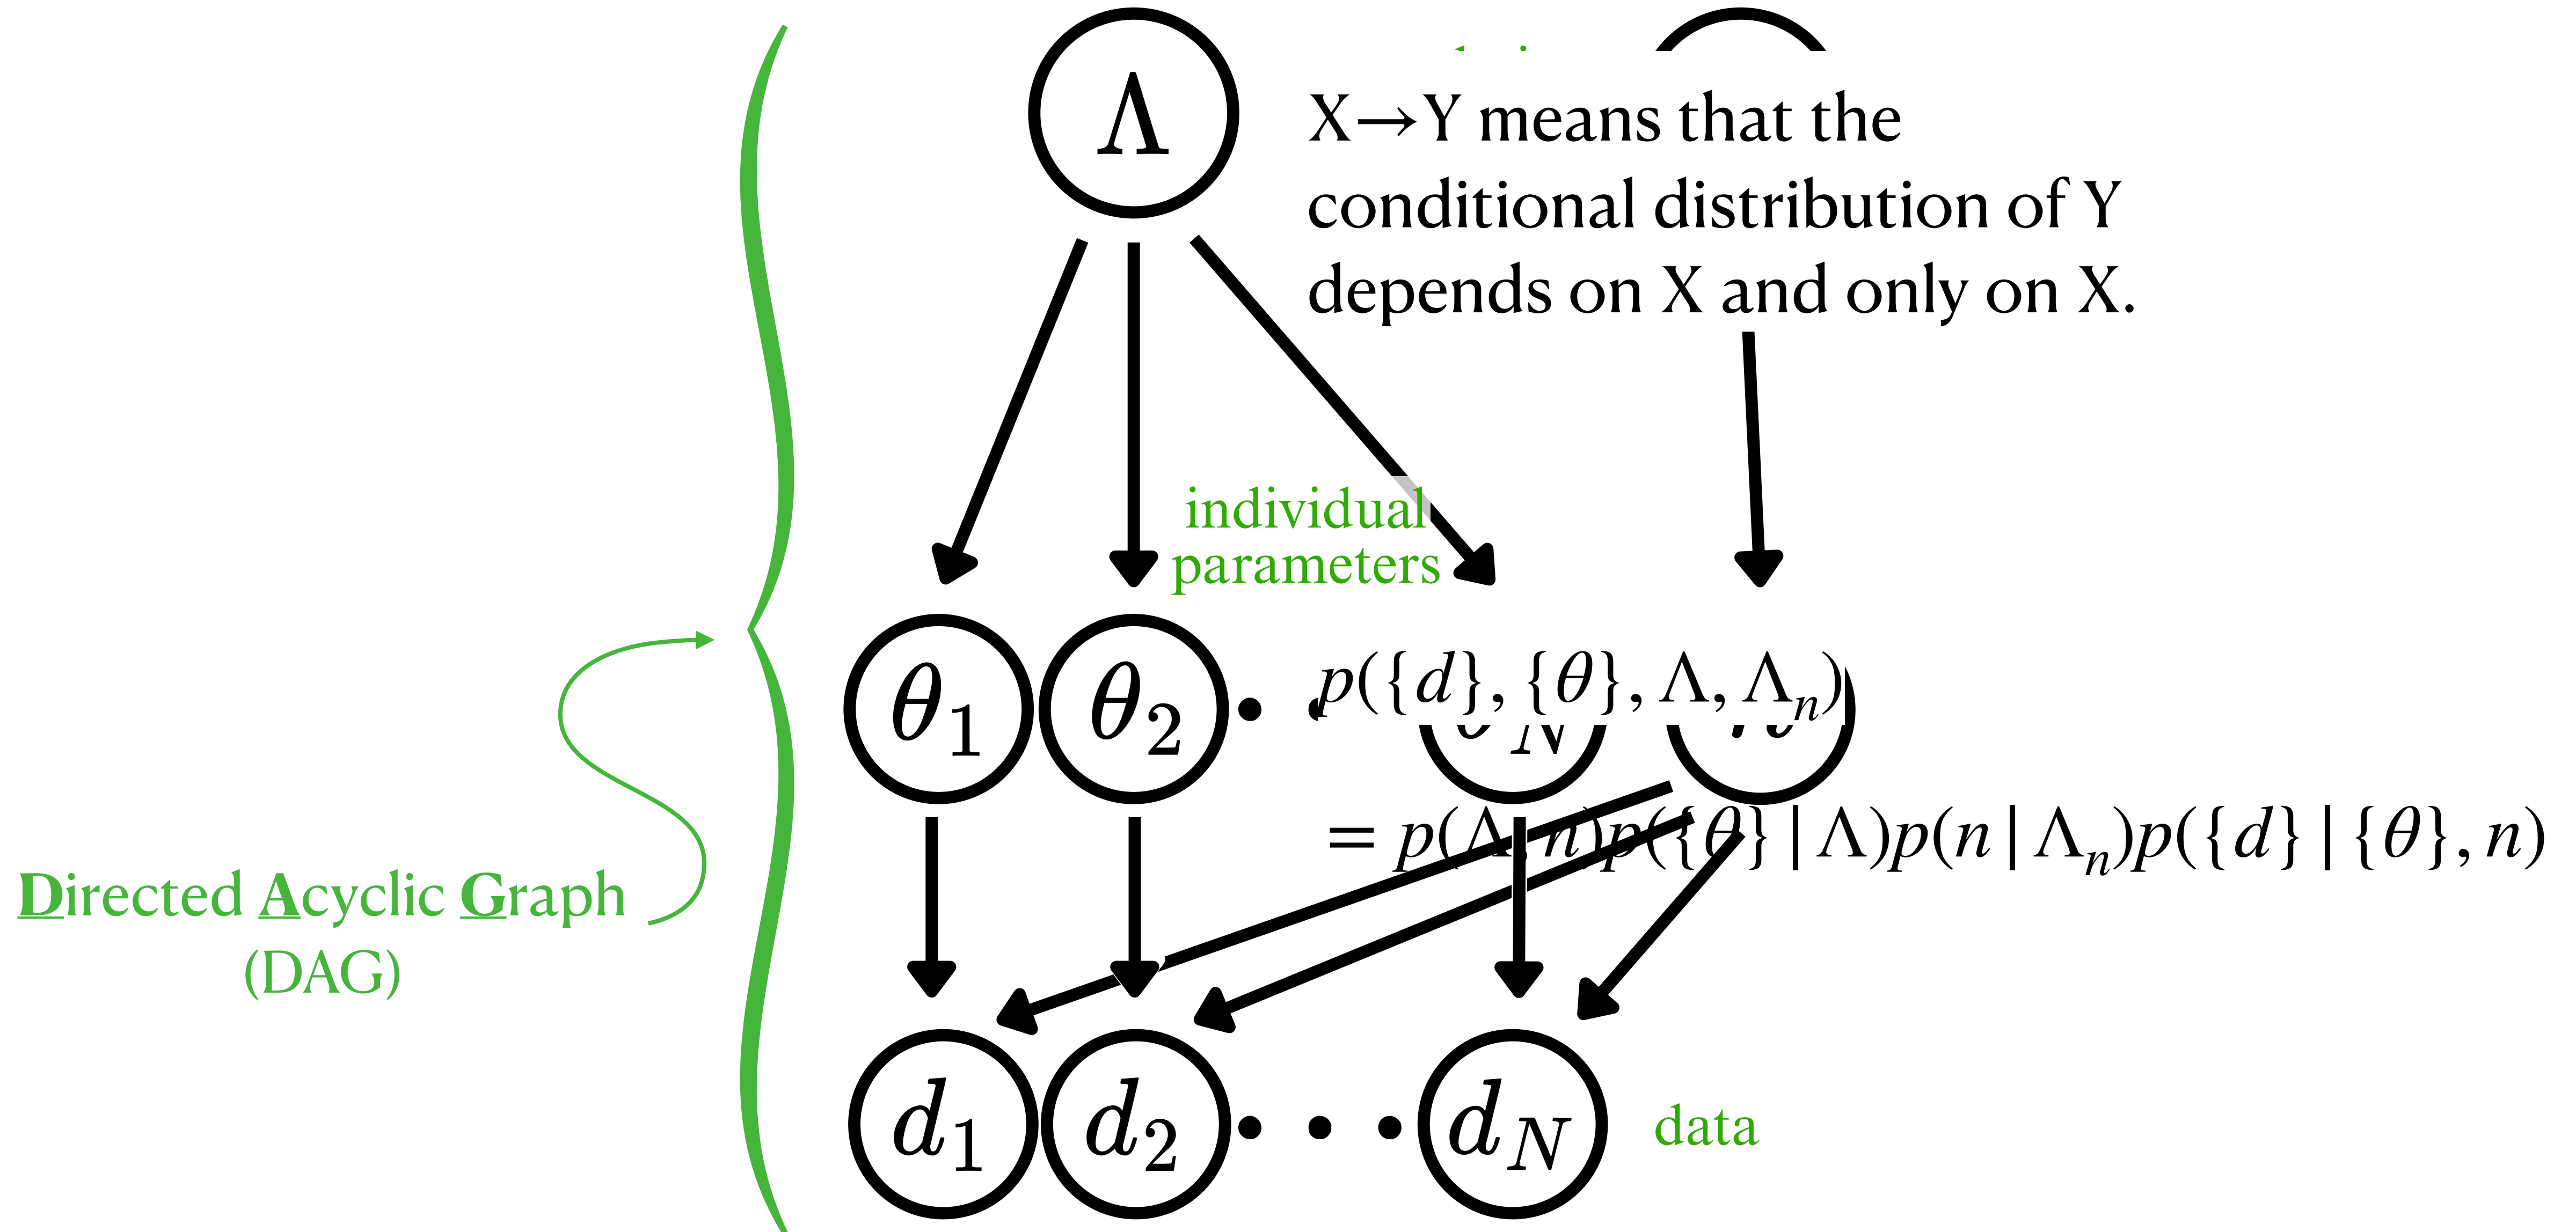

The diagram shows the joint likelihood equation for an inhomogeneous Poisson process. The equation is:
$$p(\{d\} | \{\theta\}, \Lambda) \propto e^{-N_{\text{exp}}(\Lambda)} \prod_i^{N_{\text{ev}}} p(d_i | \theta_i) \frac{dN}{d\theta}(\theta_i; \Lambda)$$
 Annotations with arrows: 'Expected number of observations' points to $N_{\text{exp}}(\Lambda)$; 'Number of observed GW events' points to N_{ev} ; 'Likelihood of observing the data from event i given that event's parameters' points to $p(d_i | \theta_i)$; 'Merger rate density' points to $\frac{dN}{d\theta}(\theta_i; \Lambda)$.

$$p(\{d\} | \{\theta\}, \Lambda) \propto e^{-N_{\text{exp}}(\Lambda)} \prod_i^{N_{\text{ev}}} p(d_i | \theta_i) \frac{dN}{d\theta}(\theta_i; \Lambda)$$

- Implementation:

`github.com/afarah18/HBA-for-GWs-tutorial`

Bonus: Getting joint posteriors from DAGs

Note on MC Variance
