# The $SL_2$ skein module and skein algebra

The  $SL_2$  **skein module** of an oriented 3-manifold  $M$  is

$$\mathcal{S}_q^{SL_2}(M) = \frac{\mathbb{C}\text{-span of isotopy classes of framed links in } M}{(\text{Kauffman bracket relations})}$$

$$\text{X} = q^{1/2} \text{ ) } ( + q^{-1/2} \text{ \smile } \text{ \frown } , \quad \bigcirc = -(q + q^{-1})$$

- If  $M = \Sigma \times (0, 1)$  is a thickened oriented surface  $\mathcal{S}_q^{SL_2}(M)$  is a **skein algebra**  $\mathcal{S}_q^{SL_2}(\Sigma)$  with multiplication given by stacking in the interval direction.

# Basis and noncommutativity of skein algebras

$$\begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \end{array} = q^{1/2} \left( \begin{array}{c} \diagup \diagdown \\ \diagup \diagdown \end{array} + q^{-1/2} \begin{array}{c} \diagup \diagup \\ \diagdown \diagdown \end{array} \right), \quad \bigcirc = -(q + q^{-1})$$

- ▶  $\mathcal{S}_q^{SL_2}(\Sigma)$  has a **standard basis** of multicurves (crossingless curves on  $\Sigma$  with no loop bounding a disk) [Przytycki '91].
- ▶ The choice of  $q \in \mathbb{C}$  influences **non-commutativity** of  $\mathcal{S}_q^{SL_2}(\Sigma)$ .
  - ▶  $q = 1$  :  $\mathcal{S}_q^{SL_2}(\Sigma)$  is commutative.
  - ▶  $q$  generic: “trivial” center.
  - ▶  $q$  a root of unity: rich center!

The center of the skein algebra is studied by using a **Frobenius homomorphism** for skein modules (Bonahon-Wong).

# Similar Frobenius homomorphisms

- ▶ (Classical) For a commutative ring  $\mathcal{R}$  of prime characteristic  $p$ , raising each **element to the  $p$ th power**  $a \mapsto a^p$  gives a ring endomorphism due to the Frobenius property:

$$(a + b)^p = a^p + b^p.$$

- ▶ (Quantum algebra) If  $A_q = \mathbb{C}\langle x_1, x_2 \mid x_1 x_2 = q x_2 x_1 \rangle$  for  $q$  a primitive  $n$  root of unity there is a Frobenius homomorphism  $A_1 \rightarrow A_q$  by raising each **generator to the  $n$ th power**  $x_i \mapsto (x_i)^n$ . The generators satisfy the Frobenius property:

$$(x_1 + x_2)^n = x_1^n + x_2^n$$

- ▶ The image is central!
- ▶ (Skein algebra) The Bonahon-Wong map goes from  $\mathcal{S}_1^{SL_2}(\Sigma) \rightarrow \mathcal{S}_q^{SL_2}(\Sigma)$  by “raising” knots to “powers.”

# The right way to raise a knot to a power

We want a map  $Fr : \mathcal{S}_1^{SL_2}(M) \rightarrow \mathcal{S}_q^{SL_2}(M)$  for  $q^n = 1$  that satisfies the skein relations. Consider the easiest skein relation. Assume  $n$  is odd for this slide.

- ▶ At  $q = 1$ ,  $\text{loop} = -2$
- ▶ At  $q^n = 1$ ,  $\text{loop} = -q - q^{-1}$
- ▶ At  $q^n = 1$ , we want  $Fr(\text{loop}) = -2 = -q^n - q^{-n}$ .

Observe:  $-q^n - q^{-n}$  is a polynomial in  $-q - q^{-1}$

$$T_n(-q - q^{-1}) = -q^n - q^{-n},$$

where  $T_n$  is defined by  $T_n(\text{tr}(A)) = \text{tr}(A^n)$  for any  $A \in \text{SL}_2$ .

It's reasonable to expect that  $Fr(\text{knot})$  is given by “replacing the knot by a polynomial of the knot.”

# Threading a polynomial along a knot

## Definition (Focus on the picture)

$K$  = framed knot in  $M$ ,  $x^i \in \mathbb{C}[x]$  = monomial, then  $K^{[x^i]} \in \mathcal{S}_q^{SL_2}(M)$  obtained by threading  $x^i$  along  $K$  is given by taking the union of  $i$  parallel copies of  $K$  in the direction of the framing.

- ▶ If  $P = \sum a_i x^i \in \mathbb{C}[x]$ , then  $K^{[P]} = \sum a_i K^{[x^i]} \in \mathcal{S}_q^{SL_2}(M)$ .
- ▶ if  $L = \cup K_j$  is a link with knot components  $K_j$  then  $L^{[P]} = \cup K_j^{[P]}$ .

e.g.,  $K^{[x^3]}$  is pictured:

# Chebyshev polynomials

The Chebyshev polynomials  $T_k, S_k \in \mathbb{Z}[x]$  are given by the following.

- ▶ (1<sup>st</sup> kind)  $T_0 = 2, T_1 = x, T_k = xT_{k-1} - T_{k-2}$ .
- ▶ (2<sup>nd</sup> kind)  $S_0 = 1, S_1 = x, S_k = xS_{k-1} - S_{k-2}$ .

They satisfy defining properties:

- ▶  $T_k(q + q^{-1}) = q^k + q^{-k}$
- ▶  $S_k(q + q^{-1}) = [k + 1]$ , where  $[m] = \frac{q^m - q^{-m}}{q - q^{-1}}$

For core loop of annulus  $x \in \mathcal{S}_q^{SL_2}(\mathcal{A}) \cong \mathbb{C}[x]$ :

- ▶  $S_k, T_k$  are involved in **positive bases** for skein algebras, unitriangularly related to the standard basis (Queffelec, Mandel-Qin, D. Thurston, Frohman-Gelca, Queffelec-Russell)

# Frobenius homomorphism for $SL_2$ skein modules

## Theorem (Bonahon-Wong '12)

*Let  $M$  be an oriented 3-manifold and  $q$  be a root of unity with  $n > 0$  being the smallest integer such that  $q^n \in \{1, -1\}$ . Set  $t := q^{n^2} \in \{1, -1\}$ . Then there exists a homomorphism of skein modules*

$$Fr : \mathcal{S}_t^{SL_2}(M) \rightarrow \mathcal{S}_q^{SL_2}(M)$$

*defined on links by  $L \mapsto L^{[T_n]}$ , by threading  $T_n$  along each component of the link.*

- ▶ The proof of Bonahon-Wong used the quantum trace map and a Frobenius map for Chekhov-Fock quantum torus.
- ▶ Lê '13 gave a purely skein theoretic proof.
- ▶  $Fr$  can be used to characterize the centers of skein algebras and study the representation theory (Bonahon-Wong '12, Frohman–Kania-Bartoszyńska–Lê '19, Ganey-Jordan-Safronov '19)

The hard thing to check is that the Frobenius homomorphism  $\mathcal{S}_t^{SL_2}(M) \rightarrow \mathcal{S}_q^{SL_2}(M)$  respects the Kauffman bracket relation e.g.:

$$T_n = t^{1/2} T_n T_n + t^{-1/2} T_n$$

when  $t^{1/2} = q^{n^2/2}$ .

- ▶ We will see how to prove this identity using Jones-Wenzl projectors at a root of unity, with an eye towards webs.
- ▶ The fact that  $T_n$  produces central elements can be generalized to other skein theories using multivariable polynomials:  
 $SL_n$  (Bonahon-H. '23),  
 $G_2$  (Beaumont-Gould-Brodsky-H.-Hogan-Melby-Piazza '23),  
 $Sp_{2n}$  (H.-Wu, '25),  
 $PGL_2$  (H.-Silva-Somers-Sundar-Stephens-Wokhlu '25).

In future work, we want to compute the image of  $Fr$  on an  $SL_2$  **web** (quantum spin network) without rewriting as links.

- ▶ Partial results forthcoming in (H.-Silva-Somers-Stephens-Sundar-Wokhlu '25)
- ▶ Work of (Rose-Tubbenhauer '15) shows similar  $SL_2$  webs called “symmetric webs” satisfy similar skein relations to Cautis-Kamnitzer-Morrison  $SL_n$  webs.

# Frobenius map for $SL_3$ skein modules

## Theorem (H. '24, Kim-Lê-Wang '25)

*There is a Frobenius homomorphism for  $SL_3$  skein modules given by threading 2-variable analogues of  $T_n$  along links.*

- ▶ K LW '25 further generalizes the map to stated  $SL_n$  skein modules of manifolds with at least 1 marked point
- ▶ Our proofs use the quantum group  $\mathcal{O}_q(SL_n)$  and are not completely skein theoretic.
- ▶ Little is known about the Frobenius image of a web.

## Theorem (H.-Kim-Wang '25)

*The image of a Kuperberg  $SL_3$  web on a surface under the Frobenius map is a  $\mathbb{Z}$ -linear combination of elements of the Sikora-Westbury non-elliptic web basis.*

# Revisiting $SL_2$

We want to understand the Frobenius homomorphism skein theoretically in a way that hopefully helps to give:

- ▶ a purely skein theoretic way to construct the Frobenius homomorphism for  $SL_3$  and beyond
- ▶ a way to compute the image of the Frobenius on a web

Some specific ingredients we want:

- ▶ skein identities which are somewhat local
- ▶ Relationships between the Frobenius elements and Jones-Wenzl projectors

# Temperley-Lieb calculus

The  $TL$  category has

- ▶ Objects: non-negative integers
- ▶ Morphisms: The Hom space  $k \rightarrow l$  is the vector space  $TL_{k,l}$  spanned by  $(k, l)$ -tangles in a rectangle modulo Kauffman bracket relations, e.g.:

- ▶ The category  $TL$  is isomorphic to the full subcategory of  $U_q(sl_2)$ -mod with objects  $V^{\otimes k}$  for the standard 2-dim rep  $V = \mathbb{C}^2$ .
- ▶ If  $q \in \mathbb{C}^\times$  is generic, idempotent completion of  $TL$  gives  $U_q(sl_2)$ -mod.

# Jones-Wenzl projectors

For generic  $q$ , the  $U_q(sl_2)$  irreps  $V_k \leftrightarrow JW_k \in TL_{k,k}$ , the Jones-Wenzl projectors defined by the following axioms:

- ▶ (1) The coefficient of  $\text{Id}_k$  of  $JW_k$  in standard basis is 1

$$\boxed{K} = 0 = \boxed{K}$$

- ▶ (2) each  $JW_k$  is “uncappable”:

- ▶ Recursive definition:

$$\boxed{1} = | \quad , \quad \boxed{2} = || + \frac{1}{[2]} \text{ (cup and cap) } , \quad \boxed{K} = \boxed{K-1} + \frac{[K-1]}{[K]} \text{ (cup and cap) } \boxed{K-1}$$

- ▶ The recursion shows  $JW_k$  exists if  $[2], [3], \dots, [k] \neq 0$ .
- ▶ Some JW projectors exist even if last point doesn't hold!

# Temperley-Lieb category at roots of unity

Let  $q \in \mathbb{C}$  be a root of unity such that  $n$  is the smallest positive integer for which  $q^n \in \{-1, 1\}$ , i.e.  $[n] = 0$  but  $[k] \neq 0$  for  $k < n$ .

- ▶ The idempotent completion of  $TL$  is the category of tilting modules of  $U_q(sl_2)$ , direct summands of  $V^{\otimes k}$  (Elias '15)
- ▶ The JW recursion implies  $JW_1, \dots, JW_{n-1} \in TL$  exist.
- ▶  $JW_n$  does not exist but  $JW_{2n-1}, JW_{3n-1}, \dots$  exist.

## $JW_{2n-1}$ at a root of unity

When  $n$  is the smallest positive integer such that  $q^n \in \{-1, 1\}$ , the projector  $JW_{2n-1}$  is given by the following formula (Martin-Spencer '21).

$$\boxed{2n-1} \approx \boxed{n-1} \boxed{n-1} + \sum_{k=1}^{n-1} (-1)^k \left( \begin{array}{c} \text{Diagram 1} \\ \text{Diagram 2} \end{array} \right)$$

- It is fast to check that this expression satisfies the axioms for  $JW_{2n-1}$ .
- You can obtain the same expression by writing  $JW_{2n-1}$  in generic  $q$  and canceling the denominators of  $[n]$  before specializing  $q$ .
- These  $JW$  projectors and other idempotents for tilting modules are constructed in Sutton-Tubbenhauer-Wedrich-Zhu '21, Martin-Spencer '21, Goodman-Wenzl '93,...

# The quantum group at roots of unity

The following provides context for the skein identities we want.

Let  $t = q^{n^2} = \pm 1$ . There is a functor of ribbon categories

$$Fr : \text{Rep}_t(SL_2) \rightarrow \text{Rep}_q(SL_2)$$

coming from Lusztig's Frobenius map  $U_q(sl_2) \rightarrow U_t(sl_2)$ .

- ▶ For the standard rep  $V^{(t)}$  of  $U_t(sl_2)$ ,  $Fr(V^{(t)})$  is not a tilting module. There is no idempotent in  $TL$  corresponding to it.
- ▶ There is a Steinberg tensor product formula (Andersen-Wen '92):

$$V_{n-1}^{(q)} \otimes Fr(V^{(t)}) \cong V_{2n-1}^{(q)}$$

- ▶  $V_{n-1}^{(q)} \leftrightarrow JW_{n-1}$  (the Steinberg module) and  $V_{2n-1}^{(q)} \leftrightarrow JW_{2n-1}$ .

# Frobenius strands

Although  $Fr(V^{(t)})$  doesn't have a corresponding idempotent in  $TL$ , the representation still manifests itself in skein module theory in two common ways:

- ▶ A knot threaded by  $T_n$  is the image of the knot under the Bonahon-Wong Frobenius map
- ▶  $n$  parallel copies of an arc is the image of an arc under certain Frobenius maps, e.g. for stated skein modules or Muller skein modules (Lê-Paprocki '18, Bloomquist-Lê '20)

We will later use the following notation to use a green strand to label either type of Frobenius strand:

# Steinberg skein identities

## Theorem (H.-Tambe '25)

The following skein identities hold when  $n$  is the smallest positive integer such that  $q^n \in \{-1, 1\}$ .

Using the green strand notation, both identities are encoded by the

local identity

- ▶ We view the identities as incarnations of the Steinberg tensor product formula  $V_{n-1} \otimes Fr(V) \cong V_{2n-1}$ .

# Threading map of Bonahon-Wong

To show that  $L \mapsto L^{[T_n]}$  gives a well-defined skein module homomorphism  $\mathcal{S}_t^{SL_2}(M) \rightarrow \mathcal{S}_q^{SL_2}(M)$ , the main identity we need to show is:

$$\begin{array}{c} T_n \quad T_n \\ \diagdown \quad \diagup \\ \diagup \quad \diagdown \end{array} = t^{1/2} \begin{array}{c} T_n \\ \cup \end{array} \begin{array}{c} T_n \\ \cup \end{array} + t^{-1/2} \begin{array}{c} T_n \\ \cap \end{array} \begin{array}{c} T_n \\ \cap \end{array}$$

in  $\mathcal{S}_q^{SL_2}(M)$  when  $t^{1/2} = (q^{1/2})^{n^2}$ .

- ▶ It will suffice to consider the identity in a thickened surface.
- ▶ It will suffice to assume the thickened surface is punctured.
- ▶ This identity doesn't seem to involve  $JW_{n-1}$ , so we need a trick in order to use our skein identities.

# The trick: multiply by 1

$$\text{[Diagram: circle with box } n-1 \text{]} = (-1)^{n-1} [n] = 0, \quad \text{but} \quad \text{[Diagram: circle with box } n-1 \text{ and a dot]} = \text{[Diagram: circle with a dot]}^{S_{n-1}}$$

- $JW_{n-1}$  closed around a puncture is not a zero divisor in the skein algebra of the surface. (Think of multiplying in the standard basis)

It will suffice to show the following identity:

$$\text{[Diagram: circle with box } n-1 \text{ and a dot]} \begin{array}{l} \diagup \\ \diagdown \end{array} = t^{v_2} \text{[Diagram: circle with box } n-1 \text{ and a dot]} \begin{array}{l} \diagup \\ \diagdown \end{array} + t^{-v_2} \text{[Diagram: circle with box } n-1 \text{ and a dot]} \begin{array}{l} \diagdown \\ \diagup \end{array}$$

Using the Steinberg identities we compute

$$\begin{aligned}
 & \text{Diagram 1} = \text{Diagram 2} = \text{Diagram 3} = \text{Diagram 4} = \text{Diagram 5} \\
 & \text{Diagram 1: Crossing with loop } n-1 \text{ on left strand.} \\
 & \text{Diagram 2: Crossing with four loops } a-1 \text{ on left strand.} \\
 & \text{Diagram 3: Crossing with loop } a-1 \text{ and loop } 2n-1 \text{ on left strand.} \\
 & \text{Diagram 4: Crossing with loop } a-1 \text{ and loop } 2a-1 \text{ on left strand.} \\
 & \text{Diagram 5: Crossing with loop } a-1 \text{ and loop } 2n-1 \text{ on left strand, and loop } 2a-1 \text{ on right strand.}
 \end{aligned}$$

Similarly,

$$\begin{aligned}
 & \text{Diagram 1} = \text{Diagram 2} = \text{Diagram 3} \\
 & \text{Diagram 1: Sum of two crossings, each with a loop } n-1 \text{ on opposite strands.} \\
 & \text{Diagram 2: Crossing with loop } a-1 \text{ and loop } 2n-1 \text{ on left strand, and loop } 2a-1 \text{ on right strand.} \\
 & \text{Diagram 3: Crossing with loop } a-1 \text{ and loop } 2n-1 \text{ on left strand, and loop } 2a-1 \text{ on right strand.}
 \end{aligned}$$

It remains to see

- ▶ This follows from rather well-known identities.
- ▶ The Steinberg identities give us a new proof that starts:

Thank you
